At San José State University, I would seek to make rigorous economics accessible to students with different levels of preparation and experience with quantitative methods. My teaching philosophy is to begin with an economic question, develop the reasoning behind the method, and then demonstrate its implications using data. Students should leave a class not only knowing how to apply a technique, but also understanding its assumptions and limitations. This approach aligns with SJSU's commitment to student success across a broad range of academic and personal backgrounds.

At Bocconi University, I have delivered lectures and problem sessions in PhD microeconometrics and macroeconometrics over four academic years, alongside teaching-assistant work in undergraduate and master's courses. I develop difficult material step by step on the whiteboard and use simulations, code, and empirical examples to make abstract results tangible. For instance, when teaching weak instruments, I first demonstrate why familiar methods can fail before introducing robust alternatives. My teaching evaluations have been strong, averaging 8.76 out of 10 across eight course-year evaluations. More importantly, I have adapted my teaching in response to feedback. After students noted that some sessions moved too quickly, I reduced the amount of material covered, allowed more time for questions, and focused on understanding rather than breadth.

At SJSU, I would bring these practices to undergraduate and graduate teaching in macroeconomics, econometrics, and forecasting. I would structure assignments so that students can move from interpreting a graph or economic question to implementing and critically assessing a statistical method. Publicly available data on inflation, employment, and economic activity, together with reproducible code and clearly staged exercises, can make quantitative research more approachable without lowering academic expectations. I would also provide transparent assessment criteria, frequent opportunities for feedback, and space for questions, recognizing that students may enter the classroom with different levels of confidence or prior access to programming and mathematics.

I would be particularly interested in helping students participate in applied research. My work on forecasting and robust inference provides opportunities for projects that begin with real economic data and build toward independent analysis. Through project supervision, accessible research materials, and constructive feedback, I would aim to give students a path into quantitative work even if they have not previously considered research as an option. I would also contribute to the Department's teaching and advising community by sharing instructional materials and learning from colleagues' experience supporting SJSU students. For me, institutional excellence means maintaining rigorous standards while making the opportunities to meet them more widely accessible.
