My goal in teaching economics is to make technically demanding material both rigorous and usable. I want students to understand why an economic or econometric method works, but also to leave the classroom knowing when it is appropriate, which assumptions matter, what can go wrong in practice, and how the method can be applied. My teaching experience so far has been concentrated in econometrics, where I try to connect theory with computation and empirical examples, but the same principle would guide my teaching in economics more broadly.

At Bocconi, I have taught PhD-level Econometrics 2 (Microeconometrics) and Econometrics 3 (Macroeconometrics) over four academic years. I have also served as a teaching assistant for Econometrics for Big Data at the master's level and two undergraduate econometrics classes. This experience has given me the opportunity to explain a variety of econometric topics to students with very different levels of technical preparation.

Teaching Evaluations

My teaching evaluations in the PhD econometrics sequence have been consistently strong. Bocconi's Faculty Performance Index summarizes students' responses on clarity, interaction, ability to stimulate interest, and teaching materials on a scale from 1 to 10.

Academic Year	Econometrics 2	Econometrics 3
2022/23	9.10	8.43
2023/24	8.36	8.17
2024/25	8.98	8.66
2025/26	9.00	9.37

Across the eight course-year evaluations, my average Faculty Performance Index is 8.76 out of 10. Qualitative feedback emphasizes my command of the material, accessibility, enthusiasm for econometrics, and ability to explain difficult concepts. One student wrote that I have "a great way to explain complex things in a simple way", while another noted that I am "very passionate about the topic which is inspiring."

Student feedback has also shaped how I teach. Earlier evaluations occasionally noted that I tried to cover too much material and moved too quickly, for instance: "The slides are a great resource to have for the future, but I think the sessions could cover a lesser amount of topics, so it doesn't feel rushed." In response, I have increasingly emphasized depth over breadth, slowing down when introducing new concepts and leaving more time for questions and difficult exercises. The improvement in my most recent evaluations—to 9.00 in Econometrics 2 and 9.37 in Econometrics 3—is encouraging, but I continue to treat teaching as an iterative process.

Teaching Approach

In the PhD econometrics sequence, my responsibilities have included problem-set sessions as well as preparing and delivering additional lectures that complement the core material. I have developed lectures on nonparametric econometrics, partial identification, weak instruments and identification-robust inference, high-dimensional statistics and double machine learning, structural VARs, and Bayesian VARs.

My usual approach is to begin with the economic or statistical problem and then introduce the theory needed to understand it. For example, in my lecture on partial identification, I start from a simple missing-data problem and then move to bounded treatment effects, interval data, entry games, moment inequalities, and inference. In my weak-instrument lecture, I first show why conventional approximations can fail before introducing identification-robust methods. In other lectures, I use simulations and code to illustrate issues such as bandwidth choice, the bias–variance trade-off, shrinkage, and the behavior of estimators in finite samples.

I also adapt the teaching format to the material. I typically develop derivations and identification arguments step by step on the whiteboard, while using slides, simulations, and code for computational examples and empirical implementation. My aim is for students to see computation not as a substitute for economic or econometric theory, but as a way to understand what theoretical results imply in practice.

Teaching Interests

I would be happy to contribute broadly to a department's teaching needs. At the undergraduate level, I would be comfortable teaching introductory and intermediate microeconomics and macroeconomics, statistics, quantitative methods, data analysis, and econometrics. I would also be happy to contribute to general economics courses in which empirical evidence and quantitative reasoning play an important role.

At the master's and PhD levels, my comparative advantage is in econometrics. I could teach core econometrics as well as more specialized courses in microeconometrics, time-series econometrics, Bayesian econometrics, forecasting, and modern computational methods. I would also be interested in developing advanced courses on partial identification, robust inference, or Bayesian methods.

Across both general economics and specialized econometrics courses, the same principle would guide my teaching: develop the underlying economic and statistical reasoning carefully, while continually connecting it to the empirical decisions researchers and policymakers face.
